

Data Appendix

This appendix has two parts. The first part of the appendix reproduces the description of our dataset, which appeared in *Part 1: An Empirical Analysis of Metering and Other Price Determinants*. The second part of the appendix shows detailed data for each country included in the paper's analyses.

A. Data discussion, reprinted from Part 1 of this project

Broadband prices are difficult to decipher and compare for several reasons. Broadband is not a homogeneous product. It is available with different download and upload speeds and other features, and frequently comes bundled with telephone and video services, each of which has its own set of features. Additionally, it is marketed in numerous ways—with contracts and promotions that vary considerably from plan to plan, even within a company. This complexity has contributed to, as the FCC's National Broadband Plan puts it, “a dearth of consistent, comprehensive, and detailed price data”¹

To address this problem we follow and build upon the approach taken by Greenstein and McDevitt (2010). In particular, we construct a new dataset from information available from Point Topic, a UK-based consultancy that compiles data on plans from the “major broadband operators” in countries around the world.²

Point Topic records some of the data, such as company name and upload and download speeds, systematically, but unfortunately many of the details necessary to characterize plans accurately were included in written notes that had no consistent pattern. Quantifying details in the notes, which included factors such as contracts, bitcaps, promotions, and rebates, was a heavily labor-intensive process.³ Often those details implied that one particular plan in the Point Topic data contained, in reality, multiple service options. For example, the notes for one plan might include statements like, “activation fee waived if user signs a 2-year contract, otherwise activation fee of \$75.” In that case, what Point Topic and probably even the Internet Service Provider (ISP) consider to be a single plan becomes two plans in our dataset: one with an activation fee and a one-year contract, and another with no activation fee and a two-year contract. These alterations become more complicated when factoring in notes on promotions and extra features.⁴

¹ Federal Communications Commission (2010b, 38).

² Specifically, we used data from Point Topic's Operator Source dataset (combining individual spreadsheets kept for each quarter, downloaded in April 2010), which has information on broadband plans offered by a large number of providers around the world.

³ One consequence of this exercise is that after months of reading the “fine print” on thousands of broadband plans, Riso has little sympathy for anyone who complains about reading the details for a single plan.

⁴ The data are complicated in many ways. For example, many records indicate prices are not uniform throughout a provider's footprint. Over a third of Bell Canada plans in our dataset note “Tariffs mentioned for Ontario region. Different services and promotional offers for Quebec region.” Other notes are less explicit; e.g. almost all Comcast plans mention that prices are applicable for Philadelphia but “may vary for other regions.” Our data are unfortunately unable to capture those regional differences within plans. In addition, some promotional prices are offered generally, whereas others are targeted specifically at existing customers or apply only to new customers. We ignore these distinctions and use the lowest available discounted price.

The final dataset yielded a total of 25,279 unique broadband plans from 169 companies in 12 quarters (2007Q1–2009Q4). Table 1 shows the breakdown of these plans by residential or business classification and other services with which they are bundled.

Table 1
Number of Broadband Plans in the Dataset by Type

Type of Broadband Plan:	Residential	Business
Standalone	8,422	8,855
Bundle with		
Fixed voice	2,800	1,299
Video, fixed voice (triple play)	2,087	55
Video	855	29
Fixed voice, mobile voice	328	170
Video, fixed voice, mobile voice	283	4
Video, mobile voice	45	15
Mobile voice	30	2
Total	14,850	10,429

The table shows that standalone plans are the most common in the dataset, followed by broadband bundled with fixed voice and broadband bundled with telephone and video—the so-called triple play. The table also shows a small number of plans bundled with mobile voice services.⁵

⁵ ISPs now appear to be bundling mobile broadband service with fixed broadband services, though that type of bundle does not appear in our dataset. In the United States, Comcast and Time Warner Cable offer Clearwire’s 4G service as an added feature in areas in which Clear offers service (<http://www.comcast.com/About/PressRelease/PressReleaseDetail.ashx?PRID=887> http://news.cnet.com/8301-1035_3-10300017-94.html). Clearwire itself sells fixed and mobile wireless broadband service as a bundle (<http://www.clear.com/shop/quickshop?id=975&market=71>).

Table 2
Distribution of Plans by Country and Company

Country	Number of Companies	Number of Plans
Australia	4	1331
Austria	2	525
Belgium	6	577
Canada	11	2050
Czech Rep.	2	309
Denmark	7	1332
Finland	3	557
France	7	464
Germany	13	1233
Greece	3	396
Hungary	4	600
Iceland	1	106
Ireland	5	1221
Italy	3	477
Japan	8	978
Luxembourg	1	67
Mexico	4	336
Netherlands	8	945
New Zealand	2	484
Norway	8	1146
Poland	5	750
Portugal	3	590
Slovakia	1	319
South Korea	4	538
Spain	6	875
Sweden	7	1487
Switzerland	4	581
Turkey	2	75
UK	10	1188
USA	29	3869

Readers should take care when interpreting these tables. The distributions of plans by type and country are potentially misleading in two ways. First, the number of plans offered by a company is not necessarily related to a company's subscriber base. For example, in our dataset Cincinnati Bell offered 177 plans over the time period while Comcast offered only 86, even though Comcast is over 60 times larger than Cincinnati Bell.⁶

⁶ At year-end 2009 Cincinnati Bell had 244,000 DSL and fiber subscribers, compared with Comcast's 15.93 million High-Speed Internet customers. See company releases at

Second, we do not know the number of subscribers to each plan. To our knowledge, those data are not available, and certainly not for the way we define plans. We therefore cannot say what a typical consumer would pay, but only what a consumer would pay if subscribing to a particular available plan. In this paper we deal, imperfectly, with these problems by including firm fixed-effects in the regressions.

Attributes of broadband plans

In addition to customer group (business or residential) and bundle type, our dataset also includes a number of variables relevant to decomposing prices and attributes. Table 3 highlights those variables.

Table 3
Relevant Variables in the Dataset

Description
Regular monthly service charge
Monthly service charge promotional rate that applies for a portion of customer lifetime
Number of months customer receives promotional rate for service charge.
Activation fee less any discounts noted
Installation fee less any discounts noted
Equipment fee less any discounts noted (generally distinct from on-going rental costs)
Misc. monthly fee required on top of those named above, if noted (usually line rental)
Monthly service charge named requires contract of at least length entered (in months)
Downstream speed
Upstream speed
Plan has a data cap (bitcap)
Amount of data transfer allowed under cap, in megabytes
Number of TV channels, excluding music/radio where possible
Price includes tax (indicator)
Annual purchasing power parity (for GDP) exchange rate as published by OECD

Table 4 shows selected summary statistics about the plans we observe. The table illustrates that bitcaps are common in many countries, with service providers in 24 of the 30 countries offering plans with bitcaps. Nine of the countries listed have bitcaps on over 50% of the plans offered. In three countries, Australia, New Zealand and Belgium, 75% or more of the plans offered contain bitcaps. While we are unaware of research explaining why caps are more common outside the United States, one possible reason is that because local landline phone calls were historically metered in countries other than the U.S., residents of those countries never experienced truly unlimited dialup service and were, therefore, less likely to expect unlimited broadband from ISPs.

<http://investor.cincinnati-bell.com/phoenix.zhtml?c=111332&p=irol-newsArticle&ID=1387040&highlight> and http://files.shareholder.com/downloads/CMCSA/845254023x0x348274/c7755491-8d6d-4027-b3ae-0a061f45fc5f/Comcast_Q4Trending_2.2.10.pdf

The table also shows that plans that bundled video packages include far more television channels in the U.S. than in other countries. The median number of channels included in a video package in the U.S. is 160, far above the amount of channels offered in most other countries. Plans in Canada offer the second-largest number at 116.

Table 4
Characteristics of Residential Broadband Plans, 2007-2009

	Median Speed (kbps)		Bitcap ⁷		Median number of video channels
	Download	Upload	Share with	Median size (GB)	
Australia	8000	256	99%	12	
Austria	8192	768	11%	5	94
Belgium	10000	256	75%	20	60
Canada	1500	640	52%	30	116
Czech Republic	3072	256	15%	20	49
Denmark	6144	1024	21%	0.05	36
Finland	2048	600	0%		
France	28000	800	0%	50	100
Germany	6144	608	1%	1.5	60
Greece	2048	256	10%	3	
Hungary	4096	480	14%	1	47
Iceland	8000		63%	6	60
Ireland	3000	256	46%	20	61
Italy	20000	1000	0%		30
Japan	26000	2000	0%		60
Luxembourg	8000	384	64%	15	
Mexico	1024	128	1%	4	83
Netherlands	8000	1024	2%	100	53
New Zealand	4000	2000	94%	20	
Norway	5000	1000	0%		33
Poland	1024	256	7%	17	40
Portugal	8192	256	61%	14	46
Slovakia	1536	256	53%	1	16
South Korea	20000	6000	0%		
Spain	6000	320	6%	1	36
Sweden	10000	3000	1%	0	27
Switzerland	5000	425	10%	0.02	100
Turkey	1024	256	27%	6	
UK	8000	448	42%	10	100
USA	5000	768	4%	250	160

Note: None of the 45 residential plans reported in Iceland (all offered by Siminn) named upload speed. Upload data is missing in over 2680 plans (vs. 184 missing download speed).

⁷ Some of the bitcaps seem, at first glance, implausibly small, but appear to be legitimate. For example, the plans in Denmark with 50 MB monthly caps also capped additional usage charges at DKK 400 (approximately USD 75) per month.

Figure 1 provides detail on triple-play video packages by showing the range of the number of channels available in video packages in each country. The figure shows that the U.S. has the highest median number of channels (160) and also the widest range of number of channels. The UK has the second highest median number of channels (140), followed by Germany (120), Canada (100), and France and Switzerland (both with 100).

Figure 1
Number of Channels Included in Residential Triple Play Packages by Country, 2007-2009

Note: Box plot shows median (diamond), 25th to 75th percentiles or interquartile range (shaded box), values within 1.5 times the interquartile range (whiskers) and outliers (dots). Channel distributions differ from Table 4 because this figure isolates triple play plans.

The number of channels included in a video package is one important indicator of the value of a video bundle. After all, video distributors themselves frequently use that indicator in their advertising. Nevertheless, other factors also affect how consumers value the bundle and how costly the programming is to the video distributors. For example, consumers may care about the availability of high-definition (HD), premium, and sports channels. Meanwhile, programmers have differing abilities to bundle their own programming and to charge the distributor. Unfortunately, we do not have any such information across countries, meaning that our channel count, while the best available, is a highly imperfect indicator of the quality of video bundles.

Creating a comparable price variable

As mentioned above, comparing broadband prices is not straightforward. Factors like promotions and miscellaneous fees mean that simply examining advertised monthly prices is likely to yield inaccurate and potentially misleading comparisons. Instead, we require a variable that is comparable across plans, companies, and countries.⁸ We create such a variable by calculating the total price a consumer would pay for a year of service for each plan, as shown in equation (1) below.

$$(1) \text{ Net price for one year} = (\text{promotional price} * \text{number of months promotion lasts}) + (\text{standard price} * (12 - \text{number of months promotion lasts})) + \text{installation fee} + \text{activation fee} + \text{equipment charges} + \text{other and hidden fees} - \text{rebates}$$

The implicit assumption behind this variable is that consumers consider their total expected payments over a year when choosing a broadband plan. Certainly, not all consumers think that way. More practically, this variable overstates payments for consumers whose plans have contracts of less than one year or no contract and who aim to shop for a new service as soon as possible. Similarly, it understates payments for consumers whose contracts exceed one year. Nevertheless, we believe the variable is appropriate because it allows for a consistent and comparable measurement of prices that takes into account many of the factors included in the price a consumer pays.

Table 5 shows some basic descriptive statistics for this variable. Specifically, the table shows the median unweighted prices of the different residential and business bundle types in the data. Because they are unweighted, they do not necessarily reflect the price a typical OECD consumer would pay, but they do give a sense of some the differences across plans. The table shows, for example, that business plans tend to be more expensive than residential plans, with the unweighted price for business more than double that for residential. Note that while the table shows the median for bundles that include mobile voice, the sample sizes for those plans are quite small, so those figures may not be especially meaningful and we do not explore them further in the analysis.

Table 5
Median Unweighted Broadband Bundle Prices Across all Countries, 2007-2009

Bundle type	Residential	Business
Standalone broadband (no bundle)	\$499	\$1,190
Bundle with		
Fixed voice	544	904
Video	674	-
Fixed voice, video ("triple play")	904	-
Fixed voice, mobile voice, video	974	-
Fixed voice, mobile voice	672	963

⁸ Note that all currency values are converted to U.S. dollars at annual purchasing power parity (PPP). All discussion and figures are presented in dollars by PPP. Rates available from the OECD at http://stats.oecd.org/Index.aspx?datasetcode=SNA_TABLE4.

Figure 2 provides additional information on the residential-business price difference. The figure shows that business plans are consistently more expensive than residential plans even where, as is the case in many countries, residential plans tend to be faster.

Figure 2
Median Net One-Year Price and Download Speed for Business and Residential Standalone Broadband Plans, 2007-2009⁹

⁹ ISO abbreviations per <http://unstats.un.org/unsd/methods/m49/m49alpha.htm>

B. Data by country

This section of the data appendix details the methods we use to approximate the distribution of downstream speeds in each country from 2007-2009 and to estimate “representative middle” prices. The representative middle, which was related less formally in Part 2 of this project, is calculated as follows.

For each (Residential standalone, Residential triple play, Business standalone):

$$\text{Weighted Median}_{ist} = \frac{1}{\text{subscribers}_{it}} \sum_j \text{median}(\text{Net One Year Price})_{jst} \times \text{subscribers}_{jt}$$

$$\text{Representative Middle Price}_{it} = \frac{1}{\text{lines}_{it}} \sum_s \text{Weighted Median}_{ist} \times \text{lines}_{ist}$$

Where

- i = OECD country
- s = speed tier, as described for country i in “Connections by speed tier” tables
- t = 1H2007, 2H2007, ... 2H2009
- j = ISP (operating within a single country)

The “subscribers” variable is derived from Point Topic firm data, whereas “line” weights are connection counts from the regulator or other market data by speed tier. “Net one year price” and other details are explained elsewhere.

The table below presents a summary of weighted median prices from 2007-2009. Countries are grouped alphabetically within common download speed tier schemes, which are dictated by the source of the tier definitions (detailed below). Note that some countries are excluded due to a lack of adequate subscriber counts or price data. Due to our high-level averaging and the roughness of download speed as a quality control, some results may appear counterintuitive (i.e. lower speeds sometimes show higher prices than a faster tier in a given market).

As shown in equations above, in order to create representative middle price indices we weight prices with fixed broadband subscriber ("line") counts. The data used for this step are detailed below. In many cases, these connection count source data are not for the exact period named, but we attempt to align the dates as well as possible. We were unable to locate reliable tier counts for several countries. Most counts combine business and residential, meaning we are forced to apply the same weights for the two groups. The exceptions are Australia and the United States, for which we employ separate connection counts by tier for business broadband.

Bracketed values in the tables indicate that the value from the named half year was also applied to the row where it is entered, due to lack of complete data. So, for example, [20072] in the tables for Australia for below mark that the counts from the second half of 2007 were also used for the first half of that year. The bar charts include these repeated data. Notes on our methodology relevant only to a specific country follow that country's connection count graph(s) when applicable. Additional notes on the sources cited for each country are found at the end of this appendix.

Tier boundaries changed in 2009 in a way which is irreconcilable with the 2007/2008 tier scheme. We apply the same “2007” data to 20071 and 20072, employ the 2008 counts for 20082, 20091, and 20092, and average these two levels for 20081.

Note: these tier definitions were too granular to allow for reliable calculation in price indexing. We employ static tier data from the EC Hungary data.

Iceland

Note: We omit Iceland from the price indices as the data are not sufficient for those analyses.

Total Connections, United States

United States, cont.

Source: FCC (2008-2010, 2010c)

Residential and business cannot be separated within speed tiers until 2H 2008 (see notes below). We use the total mix as a proxy for residential for those periods. We apply 20082 implied business counts to prior periods.

Notes on Sources

ARCEP (2010a, 2010b)

No data available for earlier than Q3 2008 as ARCEP published only high speed connections in total before that point. We ignore Q308 data when estimating 2H08 (and earlier), opting to use only the Q408 count rather than a Q3 and Q4 average. This is because Q4 2008 data which was released concurrently with Q3 2008 was revised significantly in a later publication, but no revision is found for Q3. When classifying plans into tiers in Point Topic data, we assume a plan met the upload requirement if it had over 50 Mbps downstream, even if it lacked a record of upload speed. From ARCEP (2010a) we take counts for Q4 2008 and Q1 2009; ARCEP (2010b) gives us Q2, Q3, and Q4 2009.

CRTC (2010)

We were unable to locate line counts by speed tier for Canada. These data instead detail broadband subscribers in each speed tier as estimated by official survey. We multiply the proportion of respondents in each speed category by the count of total lines (from Tables 5.3.2 and 5.3.3 of source) for each period to create tier counts. Data are annual. In the case of 2007 we use the annual count for both half years. Otherwise, we calculate averages across adjacent years to approximate midpoints (1H2008 and 1H2009). Proportions were for residential only but we have applied to both residential and business.

European Commission (2008, 2009a, 2009b, 2010)

Figures for earlier than July 2008 were not readily available. We apply July 2008 numbers to 2007. The sources claim to count “about three quarters,” “about 72%,” “about 90%”, and “only 75%” of total retail broadband lines, respectively. This may explain why in some countries (e.g. the United Kingdom) the total number of subscribers appears to decrease between the second to last and the last period, which runs counter to reliable indications of increasing wireline broadband penetration. Specific sources as follows: EC (2008) Table 5; EC (2009a) Figure 105; EC (2009b) Table 5; EC (2010) Table 3 (p. 93).

FCC (2008-2010, 2010c)

See discussion in Section III of *Part 2: International Comparisons*. We isolate fixed connections by subtracting the mobile category from the FCC connection count total, ignoring tiers with upload slower than 200 kbps. The FCC’s new tier scheme (discussed in the text of Part 2) no longer reports connections above 100 Mbps in their own tier; as such, we apply the proportion of 100 Mbps+ connections in relation to the sum of that tier and the 25-100 Mbps tier in the first half of 2008 (the last time the distinction appeared) in order to estimate a split for the new 25 Mbps+ classification in later periods. We calculate implied business counts by subtracting residential connection counts from the total counts; however, since the FCC began reporting residential counts in the second half 2008 data we can only reach business estimates for this and later periods. We assume the 2H 2008 business distribution for periods prior, whereas

for residential we use the total count in each period, as the vast majority of lines counted are to residences. FCC business counts do not include connections over dedicated access lines.

IDATE (2007,2008, 2009)

We were unable to locate exact overall subscriber counts by tier for Austria, Iceland, the Netherlands, and Norway, which are missing from the European Commission data; in addition, European Commission sources record data for Hungary for only a single period. To obtain approximations of the speed distribution within each of these countries we examined bar graphs depicting the number of subscribers by speed tier for DSL and cable modem in each country from the annual “Broadband Coverage in Europe” report from IDATE, a consulting firm. From these exhibits we recorded numerical estimates of the distribution of connections among tiers and checked those carefully “eye-balled” counts against the published totals for each market as a whole to ensure they summed correctly. We applied these annual data to the second half of each year (which unfortunately pushes them virtually a year forward from the true dates to which they correspond) and took averages of adjacent years to estimate subscribers for the 1H2008 and 1H2009. For 2007, we applied the annual figure to both half-years. As the sources altered several tier boundaries in 2009, the tiers represent a hybrid scheme we designed in order to allow for constant speed divisions across this reporting change.

NTT Corp. (2008, 2009, 2010)

We were unable to locate overall subscriber counts by tier for Japan, thus we approximate the mix of speeds with data from NTT, the incumbent Japanese provider. We define tiers based on the downstream capacity of FLET’S ADSL (NTT’s DSL services, which in our dataset do not exceed 47 Mbps down), and FLET’s Hikari/B FLET’s (its fiber network), and apply the company’s quarterly subscribership data accordingly to create a crude model of the distribution between these two speed levels in the country as a whole.

KT Corp. (2010)

We were unable to locate overall subscriber counts by tier for Korea, thus we approximate the mix of speeds with data from KT, the incumbent Korean provider.¹⁰ We define tiers around KT’s two present broadband offerings: Qook Internet Lite and Qook Internet Special. Company statements claim Lite has a maximum speed of 50 Mbps and Special has a maximum of 100 Mbps.¹¹ We generate tiers around a 50 Mbps cut-off, and average KT’s monthly data on subscribers to attain half-year subscriber counts for each tier. Note that we construct the lower tier to exclude “Megapass Checkline” plans present in the Point Topic data set which operate at 256 kbps (far lower than the next slowest plans in the country) and which an online search revealed may be related to merchant point-of-sale connections (although Point Topic classifies them as residential).

¹⁰ KT had a monthly average market share of just over half (55%) from 2007-2009.

¹¹ See excerpts of KT 20-F filings with the SEC, available at http://www.wikinvest.com/stock/Korea_Telecom_%28KTC%29/Internet%20Services
